

Myeloma Haematology and Transplant Unit Lenalidomide

This leaflet is offered as a guide to you and your family. The possible benefits of treatment vary; for some people chemotherapy may reduce the risk of the cancer coming back, for others it may control the cancer and its symptoms. Chemotherapy is the most commonly prescribed anti-cancer treatment but other types of treatment are also used. Your doctor will explain to you whether you will receive chemotherapy or another type of treatment, or a combination of both. Your doctor or nurse will be happy to answer any questions you have about your treatment. You will find it useful to refer to the booklet *Chemotherapy*, a guide which gives general information on chemotherapy and side effects.

Your treatment

Your doctor or nurse clinician has prescribed for you a tablet treatment for your myeloma. This treatment consists of 2 types of tablets: lenalidomide and dexamethasone.

These tablets are given in cycles, each cycle lasting 28 days (see information sheet overleaf).

Lenalidomide belongs to a group of drugs called immuno-modulatory agents. The tablet is taken daily for 21 days with a 7 day rest period (28 day cycle). It is important to drink plenty of fluids when taking this tablet as it can affect kidney function (up to three litres a day).

Dexamethasone are steroid tablets taken for four days, repeated three times in each cycle. These tablets should be taken with food. It is better to take them earlier in the day, since they can keep you awake if taken in the evening.

You will have a routine blood test before the start of each cycle.

This treatment can have serious or possibly life-threatening side effects. It is very important that you report side effects straight away. Don't delay, if you feel unwell, please ring The Christie Hotline on 0161 446 3658. The lines are open 24 hours a day.

Possible side effects

Chemotherapy can cause many different side effects. Some are more likely to occur than others. Everyone is different and not everyone gets all the side effects. Most side effects are usually temporary, but in some rare cases they can be life-threatening. It is important to tell your hospital doctor or nurse about any side effects so they can be monitored and, where possible, treated.

Common side effects (more than 1 in 10)

Increased risk of serious infection

You are vulnerable to infection while you are having chemotherapy. Minor infections can become life-threatening in a matter of hours if left untreated. Symptoms of infection include fever, shivering, sweats, sore throat, diarrhoea, discomfort when you pass urine, cough or breathlessness. We recommend that you use a digital thermometer so you can check your temperature. You can buy one from your local chemist.

If your temperature is 37.5°C or above or below 36°C or you have symptoms of an infection, contact The Christie Hotline straight away.

Anaemia (low number of red blood cells)

While having this treatment you may become anaemic. This may make you feel tired and breathless. Let your doctor or nurse know if these symptoms are a problem. You may need a blood transfusion.

Bruising or bleeding

This treatment can reduce the production of platelets which help the blood clot. Let your doctor know if you have any unexplained bruising or bleeding, such as nosebleeds, bloodspots or rashes on the skin, and bleeding gums. You may need a platelet transfusion.

Blood clots/ thrombosis

This treatment can increase the risk of deep vein thrombosis (DVT) and pulmonary embolism (PE). You are likely to be prescribed an anti-clotting agent such as aspirin or Dalteparin (fragmin) injection to prevent blood clots from forming. Please report immediately to your doctor or nurse if you develop a red and swollen leg or sudden onset of shortness of breath.

Peripheral neuropathy (tingling & numbness in toes or fingers)

Lenalidomide can cause nerve damage. This causes numbness or pins and needles in your fingers or toes, and muscle cramps and weakness in the legs. *It is important to tell us if this happens* as the dose of lenalidomide may have to be reduced or stopped. This is usually mild or temporary, but can last for some time. However, it can become permanent, so please report these symptoms promptly to the myeloma nurse specialist or your doctor.

Steroid side effects

Take the **dexamethasone tablets** with food as they may cause indigestion. The tablets may also increase your appetite. It is better to take them earlier in the day, for example with breakfast and lunch, since they can make you feel more alert and prevent sleep.

Dexamethasone tablets can alter your mood causing you to feel low, irritable or agitated. Please tell your doctor or nurse if this is a problem.

• **Blood sugar** - Dexamethasone can cause your blood sugar to rise. If you are diabetic then you may need to increase the dose of any diabetic medication you take (insulin or tablets). You should discuss this with your doctor before starting the treatment. Dexamethasone can also induce diabetes in people not known to have this disease. This is normally reversible although you may need to take some diabetic medication while you are having treatment.

Uncommon side effects (less than 1 in 10)

Gastrointestinal disturbance

This treatment can cause constipation, diarrhoea, nausea, an increase or decrease in weight. Please report this to your nurse or doctor if you have any of these symptoms. You may be given medication to help with any of these side effects.

Serious and potentially life threatening side effects

In a small proportion of patients chemotherapy can result in very severe side effects which may rarely result in death. The team caring for you will discuss the risk of these side effects with you.

Sex, contraception & fertility

- Lenalidomide is a known teratogen that may cause severe life-threatening birth defects.
- To ensure that an unborn baby is not exposed to Lenalidomide, your doctor will
 complete an Authorisation Form with each prescription. The form documents that
 you have given consent for Lenalidomide treatment and have been told about the
 risks to an unborn baby and the precautions you must take.

Late side effects

Some side effects may become evident only after a number of years. In reaching any decision with you about treatment, the potential benefit you receive from treatment will be weighed against the risks of serious long term side effects to the heart, lungs, kidneys and bone marrow. With some drugs there is also a small but definite risk of developing another cancer. If any of these problems specifically applies to you, the doctor will discuss these with you and note this on your consent form.

Contacts

If you have any general questions or concerns about your treatment, please contact the myeloma nurse specialist or the Haematology and Transplant Unit.

•	Myeloma nurse specialist	0161 446 8167
•	Haematology and Transplant Unit	0161 446 3925
•	General enquiries	0161 446 3000
